## Question 1: Saratoga House Prices

### Linear Model

In order to accurately predict housing prices given a house's unique features, It is important to examine trends in pricing. To this end, I will examine the existing (medium model) and attempt to improve its predictive power and accuracy. The original model is a linear model that takes into account only a few elements from the available dataset.

```
function (file, header = TRUE, sep = ",", quote = "\"", dec = ".",  
  fill = TRUE, comment.char = "", ...)  
read.table(file = file, header = header, sep = sep, quote = quote,  
  dec = dec, fill = fill, comment.char = comment.char, ...)  
<bytecode: 0x00000000127e7d50>  
<environment: namespace:utils>
```

```
[1] 62417.53
```

This value indicates the RMSE of the initial linear model I will set out to improve on. I believe that I can lower this out of sample error by including more of the house elements included in the data set. Doing so yields an out of sample error of:

```
[1] 55002.74
```

This new linear model appears to improve on the previous model in terms of out sample error. This new model takes into account all values available except for whether or not there a sewer nearby, how many fireplaces there are

### Important Factors

In order to determine what factors contribute more significantly to this model performing better in predicting house prices, I tried two methods. The first being examining the prediction error changes when I drop a certain variable. The variables that immediately stood out were land value and lot size. Due to how slow this method was and my own personal propensity to overlook variables, I tested the variables using a lasso net in order to find out which variables appear to be more important.

Table 1

intercept

lotSize

age

landValue

livingArea

From this tab

## Nonparamet

The best pred

le we can see what variables appear to “leap” first from

ictive model for housing prices may not be a linear one, or a parametric one for that matter. In order to

For the following KNN model, I will use 3 as the value of K as it minimizes out of sample prediction error. I will now test the new model across multiple train-test splits in order to get the average performance of this model.

```

result
Min.    :27220
1st Qu.:33953
Median :36041
Mean    :36302
3rd Qu.:37798
Max.    :47410

```

This non parametric model appears to significantly outperform both previous models. In summary, the final model is the most accurate among the three in predicting house prices in Saratoga.

## Question 2: Hospital Audit

### Conservative Radiologists

In this audit, I will be examining the performance of radiologists in deciding to recall and ultimately catch whether or not a patient has cancer. The first question I am going to answer is whether or not certain radiologists are more conservative, or more likely to recall a patient controlling for factors such as history, age, etc.

```
# weights: 17 (16 variable)
initial value 684.136267
iter 10 value 411.871589
iter 20 value 400.100732
final value 399.992800
converged
```

Residual Std. Error	61,169.820 (df = 1370)
F Statistic	201.805*** (df = 11; 1370)
=====	

Notes: \*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.  
 \*Significant at the 10 percent level.

```

      recall
cancer  0  1
      0 177 13
      1   3  4
  
```

```

      recall
cancer  0  1
      0 157 33
      1   2  5
  
```

I use a multinomial logit model with the specific intention to examine the changes in probability of recall for each radiologist. Based on the results, I construct confusion matrices to examine the relative differences between certain radiologists. Radiologist 89 recalled significantly more patients than radiologist 34. Thus, holding patient risk factors equal, some radiologists appear to recall patients at higher rate and could be considered more conservative.

## Weighing Factors

In order to determine whether or not radiologists should be weighing certain risk factors differently, I am going to examine what happens to the impact on accuracy inclusion of different risk factors have on predicting cancer outcomes of patients.

```

According to the data, taking family history into account actually yields worse results than a model where the decision to recall is the only factor. Going further, including all other risk factors also appears to reduce the predictive power of the model. If the radiologist were to appropriately take into account these risk factors, the model including all of the risk factors should do improve on the model where the only consideration is patient recall, which is not what this data is showing.

## Question 3: Viral Articles

Knowing the secret formula of why articles go viral and how one can consistently use that formula would be exceeding useful for marketing purpose. To this end I will be trying to estimate a model for predicting if an article would go viral. I will be comparing a model that estimates amount of shares and a probabilistic model that predicts whether or not a model exceeds a threshold that qualifies it as “going viral”.

### Part 1: Modeling number of shares

For this first model, I will be estimating a model that predicts the amount of shares that an article would get given certain characteristics. Due to the distribution of number of shares of articles, I will be using the log of shares as my variable of interest.

The model predicted that 76% of the articles went viral while only 49% of the articles went viral.

## Part 2: Predicting if an article is going to go viral

Now lets examine a probablistic model predicting whether or not an article exceeds a “viral” threshold.

```

n_TRUE n_TRUE n_TRUE n_TRUE
16256  15698   3826   3864

```

The Logit model Appears to produce better results. The last Values printed is the confusion matrix.
